

Generative AI & Phishing

Generative AI

Generative AI refers to artificial intelligence tools that can create content—like text, images, or code—based on input it receives.

Generative AI

- ChatGPT (writes emails, essays, code)
- DALL·E or Midjourney (generates images)
- ElevenLabs or AI voice cloning tools (create human-like voices)

Generative AI

These tools are not inherently bad, but attackers can use them to craft phishing emails that are:

- More realistic
- Better written
- Harder to spot

Criminals & Generative AI

- Polished, Error-Free Emails
 - No more awkward grammar or weird phrases
 - AI-generated emails look like they came from native speakers or professionals
- Role-Specific Language
 - AI can generate emails that sound like they're from HR, IT, or a CEO
 - Attackers feed in job titles or scenarios to make the message more believable

Criminals & Generative AI

- Mass Personalization
 - Tools like ChatGPT can write dozens of unique emails with just a few inputs
 - This helps attackers target many people without copy-paste repetition
- Realistic Conversation Starters
 - Some AI-powered phishing campaigns begin with a friendly or helpful message
 - Then they escalate toward malicious intent once trust is built

What This Means for You

AI has removed many of the signs we used to look for:

- Bad spelling? Not anymore.
- Strange phrasing? AI makes it fluent.
- Generic messages? Now they're customized for you.

This means it's more important than ever to slow down, verify, and stay skeptical—even if an email looks "perfect."

Key Takeaway

Generative AI has made phishing attacks smarter, faster, and more believable. That's why awareness—not just software—is your best defense.
